

Quick recap

POST When you make a POST request, you have to encode the data in the body of the HTTP request in some way

HTML forms gives us 3 methods of encoding:

- 1 | application/x-www-form-urlencoded (the default)
- 2 | multipart/form-data
- 3 | text/plain (don't use this)

Work was being done on adding application/json, but that has been **ABANDONED**

Note: there are other encodings that are possible with HTTP requests generated outside of HTML form submissions (for example, when working with AJAX, JSON is a common format for use with web services).

Let's continue to the next lecture my dear students.
